Cyclocytogenetic effect of 1-beta-D-arabinofuranosylcytosine in dividing human peripheral blood lymphocytes. Frequency of chromatid exchanges in human peripheral blood lymphocytes treated with 1-beta-D-arabinofuranosylcytosine (ara-C) was evaluated by means of the cyclo-MMC test and the MMC-stimulated direct counting of chromosome fragments. ara-C was found to be genotoxic in human blood lymphocytes with a maximal effect on day 5. The total yield of chromatid exchanges induced by ara-C (0.1 mM) after 1 hr treatment of mitotic cells was approximately 6 times higher than that induced by mitomycin C (MMC). The mitotic index (MI) was significantly decreased by all concentrations of ara-C. The MMC-stimulated direct counting of chromosome fragments and morphometric evaluation of MMC induced chromosome aberrations revealed that ara-C was more effective than MMC in inducing chromosome aberrations. Induction of chromosome aberrations was correlated with MI. Further studies showed that ara-C induced chromosome aberrations even in cells with MI lower than 5%. These results support the idea of the non-synchronous replication of lymphocytes treated with ara-C.

Postural stability of the elderly and its relation with the type of footwear used. An extremely high percentage of falls in the elderly is attributable to postural instability. The aim of this study was to measure postural stability and analyze its relations with the type of footwear used. The sample consisted of 60 elderly females (mean age: 80.9 years; SD: 4.3) who had fallen at least once in the
